Create a function with variable length of arguments

Write a program to create function func1() to accept a variable length of arguments and print their value.

Note: Create a function in such a way that we can pass any number of arguments to this function and the function should process them and display each argument's value.

Example:

Input:

```
# Call function with 3 arguments
func1(20, 40, 60)
# Call function with 2 arguments
func1(80, 100)
```

Output:

```
Printing values

20

40

60

Printing values

80

100
```
